

AI Server Power Supply Scale

Overview

AI servers consume significantly more power than traditional IT equipment, primarily due to the use of GPUs and high-performance accelerators. Typical ranges include: • Traditional servers: 300–800 W per server • GPU servers: 2–10 kW per server • AI racks: 20–100+ kW per rack

Artificial Intelligence is rapidly transforming data centres. This shift is not just about compute. Designed for traditional server configurations, conventional power-supply units (PSUs) can't efficiently keep pace with the demands. As AI servers scale to meet datacenter demand, power delivery is becoming one of the most critical and complex engineering challenges, with persistent implications for semiconductor test. It's no longer true that power delivery and measurement are peripheral steps in the test flow. The combination of Infineon's application. The rapid scaling of artificial intelligence (AI) servers and hyperscale data centers is driving new requirements for high efficiency, high density power supply unit (PSU) architectures. AI workloads demand precise power delivery, fast transient response, and robust isolation to support GPUs. utions that adhere to strict standards.
