

SRS value of optical transmitter

Overview

SRS(max) is NORMATIVE for all OLT RX over the entire transmitter compliance region. Stimulated Raman scattering (SRS) is a non-linear effect of optical fibers. When signals of different wavelengths are transmitted over an optical fiber, the energy of a shorter wavelength is transferred to a longer wavelength (between any two wavelengths). Tables from petrilla_01-0415_mmf are repeated to show the differences in link model attributes between 100G SR4 and 400G SR16 cases. It specifies a module's capability to perform in harsh environments and helps network operators determine the maximum reach or link margin available in the system. This is a power penalty metric that describes how much extra power is required from a transmitter, relative to an ideal transmitter, to compensate for both non-ideal transmitter waveforms and the impact of. uple placed on the back of the module behind the optical d TX TF) The transmitter rise and f easure of the amplitude of the c fluctuations to the electri-cal noise in the receiver relative to the signal power.
