

Transmission distance of single-mode fiber and multimode fiber

Overview

Single-mode (OS1/OS2): Guides light in a single, straight path through a tiny $9\mu\text{m}$ core, enabling long-distance, high-speed transmission. $5\mu\text{m}$), prioritizing cost and ease of use for. Dispersion limits fiber optic transmission distance by causing signal distortion and is classified into chromatic dispersion, modal dispersion, and polarization mode dispersion (PMD). Chromatic dispersion This is a key factor affecting single mode fiber distance. For example, a fiber optic cable with a distance of 1km supports a bandwidth of 500MHz, while a fiber optic cable with a distance of 2km can only support a bandwidth of 250MHz. There are three main reasons for this: First, high-bandwidth. Choosing between single mode and multimode fiber is a common decision when designing, deploying, or upgrading fiber optic networks. Although they can do the same job in some instances, the different construction methods make each of them better suited to certain tasks and budgets.
